Summary and Outlook

What is Python?

Python: Dynamic programming language which supports several different programming paradigms:

- Procedural programming
- Object oriented programming
- Functional programming

Standard: Python byte code is executed in the Python interpreter (similar to Java)

→ **platform independent code**

Why Python?

- Extremely versatile language
 - Website development, data analysis, server maintenance, numerical analysis, ...
- Syntax is clear, easy to read and learn (almost pseudo code)
- Common language
- Intuitive object oriented programming
- Full modularity, hierarchical packages
- Comprehensive standard library for many tasks
- Big community
- Simply extendable via C/C++, wrapping of C/C++ libraries
- **Focus: Programming speed**

History

- Start implementation in December 1989 by [Guido van Rossum](#) (CWI)
- 16.10.2000: [Python 2.0](#)
 - Unicode support
 - Garbage collector
 - Development process more community oriented
- 3.12.2008: [Python 3.0](#)
 - Not 100% backwards compatible
- 2007 & 2010 most popular programming language (TIOBE Index)
- Recommendation for scientific programming ([Nature News](#), NPG, 2015)
- Current version: [Python 3.9.2](#)
- [Python2](#) is out of support!¹

Zen of Python

- 20 software principles that influence the design of Python:

- 1 Beautiful is better than ugly.
- 2 Explicit is better than implicit.
- 3 Simple is better than complex.
- 4 Complex is better than complicated.
- 5 Flat is better than nested.
- 6 Sparse is better than dense.
- 7 Readability counts.
- 8 Special cases aren't special enough to break the rules.
- 9 Although practicality beats purity.
- 10 Errors should never pass silently.
- 11 Unless explicitly silenced.
- 12 ...

Is Python fast enough?

- For user programs: Python is fast enough!
- Most parts of Python are written in C
- For compute intensive algorithms: Fortran, C, C++ might be better
- Performance-critical parts can be re-implemented in C/C++ if necessary
- First analyse, then optimise!

Hello World!

hello_world.py

```
#!/usr/bin/env python3  
  
# This is a commentary  
print("Hello world!")
```

```
$ python3 hello_world.py  
Hello world!  
$
```

```
$ chmod 755 hello_world.py  
$ ./hello_world.py  
Hello world!  
$
```

Hello User

hello_user.py

```
#!/usr/bin/env python3

name = input("What's your name? ")
print("Hello", name)
```

```
$ ./hello_user.py
What's your name? Rebecca
Hello Rebecca
$
```

Strong and Dynamic Typing

Strong Typing:

- Object is of exactly one type! A string is always a string, an integer always an integer
- Counterexamples: PHP, JavaScript, C: `char` can be interpreted as `short`, `void *` can be everything

Dynamic Typing:

- No variable declaration
- Variable names can be assigned to different data types in the course of a program
- An object's attributes are checked only at run time
- **Duck typing** (an object is defined by its methods and attributes)

When I see a bird that walks like a duck and swims like a duck and quacks like a duck, I call that bird a duck.²

Example: Strong and Dynamic Typing

types.py

```
#!/usr/bin/env python3
number = 3
print(number, type(number))
print(number + 42)
number = "3"
print(number, type(number))
print(number + 42)
```

```
3 <class 'int'>
45
3 <class 'str'>
Traceback (most recent call last):
  File "types.py", line 7, in <module>
    print(number + 42)
TypeError: can only concatenate str (not "int") to str
```

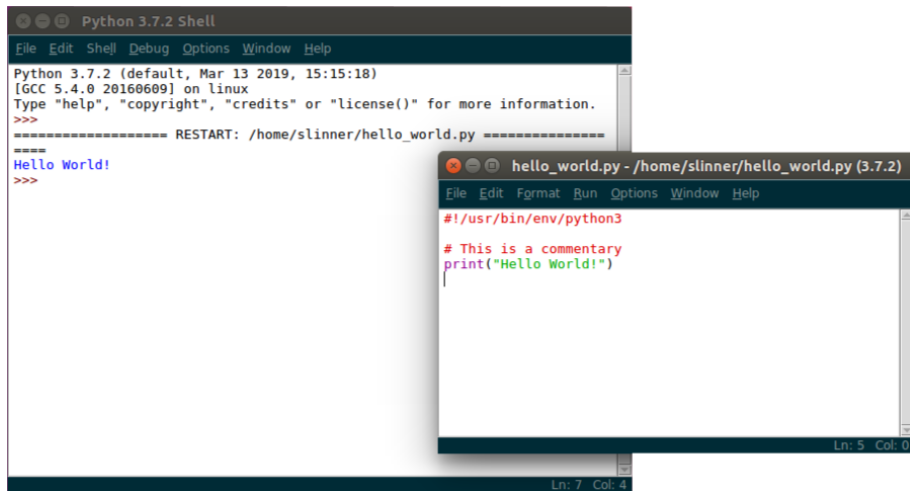

Interactive Mode

The interpreter can be started in interactive mode:

```
$ python3
Python 3.7.2 (default, Mar 13 2019, 15:15:18)
[GCC 5.4.0 20160609] on linux
Type "help", "copyright", "credits" or "license" for
more information.
>>> print("hello world")
hello world
>>> a = 3 + 4
>>> print(a)
7
>>> 3 + 4
7
>>>
```

IDLE

- Integrated DeveLopment Environment
- Part of the Python installation

The image shows two windows from the IDLE Python 3.7.2 environment. The background window is the 'Python 3.7.2 Shell', which displays the Python version, GCC version, and a 'Hello World!' message. The foreground window is a script editor titled 'hello_world.py - /home/slinner/hello_world.py (3.7.2)', showing a Python script with a shebang line, a comment, and a print statement.

```
Python 3.7.2 Shell
File Edit Shell Debug Options Window Help
Python 3.7.2 (default, Mar 13 2019, 15:15:18)
[GCC 5.4.0 20160609] on linux
Type "help", "copyright", "credits" or "license()" for more information.
>>>
===== RESTART: /home/slinner/hello_world.py =====
>>>
Hello World!
>>>
```

```

File Edit Format Run Options Window Help
#!/usr/bin/env/python3

# This is a commentary
print("Hello World!")
Ln: 5 Col: 0
```

Ln: 7 Col: 4

Documentation

Online help in the interpreter:

- **help()**: general Python help
- **help(obj)**: help regarding an object, e.g. a function or a module
- **dir()**: all used names
- **dir(obj)**: all attributes of an object

Official documentation: <http://docs.python.org/>

Documentation

```
>>> help(dir)
Help on built-in function dir:
...
>>> a = 3
>>> dir()
['__builtins__', '__doc__', '__file__', '__name__', 'a']
>>> help(a)
Help on int object:
...
```

Differences Python 2 – Python 3 (incomplete)

	Python 2	Python 3
shebang ¹	<code>#!/usr/bin/python</code>	<code>#!/usr/bin/python3</code>
IDLE cmd ¹	<code>idle</code>	<code>idle3</code>
print cmd (syntax)	<code>print</code>	<code>print()</code>
input cmd (syntax)	<code>raw_input()</code>	<code>input()</code>
unicode	<code>u"..."</code>	all strings
integer type	<code>int/long</code>	<code>int</code> (infinite)
...	hints in each chapter

Tools

Regular Expressions (optional)

Summary and Outlook

Numerical Data Types

- `int` : integer numbers (infinite)
- `float` : corresponds to `double` in C
- `complex` : complex numbers (`j` is the imaginary unit)

```
a = 1
```

```
c = 1.0
```

```
c = 1e0
```

```
d = 1 + 0j
```

Operators on Numbers

- **Basic arithmetics:** `+`, `-`, `*`, `/`

hint: *Python 2* \Rightarrow $1/2 = 0$

Python 3 \Rightarrow $1/2 = 0.5$

- **Div and modulo operator:** `//`, `%`, `divmod(x, y)`

- **Absolute value:** `abs(x)`

- **Rounding:** `round(x)`

- **Conversion:** `int(x)`, `float(x)`, `complex(re [, im=0])`

- **Conjugate of a complex number:** `x.conjugate()`

- **Power:** `x ** y`, `pow(x, y)`

Result of a composition of different data types is of the “bigger” data type.

Bitwise Operation on Integers

Operations:

- **AND:** `x & y`
- **OR:** `x | y`
- **exclusive OR (XOR) :**
`x ^ y`
- **invert:** `~x`
- **shift right n bits:** `x >> n`
- **shift left n bits:** `x << n`

Use `bin(x)` to get binary representation string of `x`.

```
>>> print(bin(6), bin(3))
0b110 0b11
>>> 6 & 3
2
>>> 6 | 3
7
>>> 6 ^ 3
5
>>> ~0
-1
>>> 1 << 3
8
>>> pow(2,3)
8
>>> 9 >> 1
4
>>> print(bin(9), bin(9>>1))
0b1001 0b100
```

Strings

Data type: `str`

- `s = 'spam'`, `s = "spam"`
- Multiline strings: `s = """spam"""`
- No interpretation of escape sequences: `s = r"sp\nam"`
- Generate strings from other data types: `str(1.0)`

```
>>> s = """hello
... world"""
>>> print(s)
hello
world
>>> print("sp\nam")
sp
am
>>> print(r"sp\nam")    # or: print("sp\\nam")
sp\nam
```

String Methods

- Count appearance of substrings: `s.count(sub [, start[, end]])`
- Begins/ends with a substring? `s.startswith(sub[, start[, end]])`,
`s.endswith(sub[, start[, end]])`
- All capital/lowercase letters: `s.upper()`, `s.lower()`
- Remove whitespace: `s.strip([chars])`
- Split at substring: `s.split([sub [,maxsplit]])`
- Find position of substring: `s.index(sub[, start[, end]])`
- Replace a substring: `s.replace(old, new[, count])`

More methods: `help(str)`, `dir(str)`

Lists

Data type: `list`

- `s = [1, "spam", 9.0, 42] , s = []`
- **Append an element:** `s.append(x)`
- Extend with a second list: `s.extend(s2)`
- Count appearance of an element: `s.count(x)`
- Position of an element: `s.index(x[, min[, max]])`
- Insert element at position: `s.insert(i, x)`
- Remove and return element at position: `s.pop([i])`
- **Delete element:** `s.remove(x)`
- Reverse list: `s.reverse()`
- **Sort:** `s.sort([cmp[, key[, reverse]]])`
- Sum of the elements: `sum(s)`

Tuple

Data type: `tuple`

- `s = 1, "spam", 9.0, 42`
`s = (1, "spam", 9.0, 42)`
- Constant list
- Count appearance of an element: `s.count(x)`
- Position of an element: `s.index(x[, min[, max]])`
- Sum of the elements: `sum(s)`

Tuple

Data type: `tuple`

- `s = 1, "spam", 9.0, 42`
`s = (1, "spam", 9.0, 42)`
- Constant list
- Count appearance of an element: `s.count(x)`
- Position of an element: `s.index(x[, min[, max]])`
- Sum of the elements: `sum(s)`

Multidimensional tuples and lists

- List and tuple can be nested (mixed):

```
>>> A = ([1, 2, 3], (1, 2, 3))
>>> A
([1, 2, 3], (1, 2, 3))
>>> A[0][2] = 99
>>> A
([1, 2, 99], (1, 2, 3))
```

Lists, Strings and Tuples

- Lists are **mutable**
- Strings and tuples are **immutable**
 - No assignment `s[i] = ...`
 - No appending and removing of elements
 - Functions like `x.upper()` return a new string!

```
>>> s1 = "spam"
>>> s2 = s1.upper()
>>> s1
'spam'
>>> s2
'SPAM'
```

Operations on Sequences

Strings, lists and tuples have much in common: They are **sequences**.

- Does/doesn't s contain an element?

`x in s` , `x not in s`

- **Concatenate sequences:** `s + t`

- Multiply sequences: `n * s` , `s * n`

- **i-th element:** `s[i]` , i-th to last element: `s[-i]`

- Subsequence (slice): `s[i:j]` , with step size k: `s[i:j:k]`

- Subsequence (slice) from beginning/to end: `s[:-i]` , `s[i:]` , `s[:]`

- **Length** (number of elements): `len(s)`

- **Smallest/largest element:** `min(s)` , `max(s)`

- Assignments: `(a, b, c) = s`

→ `a = s[0]` , `b = s[1]` , `c = s[2]`

Indexing in Python

positive index	0	1	2	3	4	5	6	7	8	9	10
element	P	y	t	h	o	n		K	u	r	s
negative index	-11	-10	-9	-8	-7	-6	-5	-4	-3	-2	-1

```
>>> kurs = "Python Kurs"
>>> kurs[2:2]

>>> kurs[2:3]
t
>>> kurs[2]
t
>>> kurs[-4:-1]
Kur
>>> kurs[-4:]
Kurs
>>> kurs[-6:-8:-1]
no
```

Boolean Values

Data type **bool**: `True` , `False`

Values that are evaluated to `False` :

- `None` (data type `NoneType`)
- `False`
- `0` (in every numerical data type)
- Empty strings, lists and tuples: `''` , `[]` , `()`
- Empty dictionaries: `{}`
- Empty sets `set()`

All other objects of built-in data types are evaluated to `True` !

```
>>> bool([1, 2, 3])
True
>>> bool("")
False
```

References

- Every object name is a reference to this object!
- An assignment to a new name creates an additional reference to this object.
Hint: copy a list with `s2 = s1[:]` or `s2 = list(s1)`
- Operator `is` compares two references (identity),
operator `==` compares the contents of two objects
- Assignment: different behavior depending on object type
 - Strings, numbers (simple data types): create a new object with new value
 - Lists, dictionaries, ...: the original object will be changed

Reference - Example

```
>>> x=1  
>>> y=x  
>>> x is y  
True  
>>> y=2  
>>> x is y  
False
```

Reference - Example

```
>>> x=1
>>> y=x
>>> x is y
True
>>> y=2
>>> x is y
False
```

Reference - Example

```
>>> x=1
>>> y=x
>>> x is y
True
>>> y=2
>>> x is y
False
```

Reference - Example

```
>>> x=1  
>>> y=x  
>>> x is y  
True  
>>> y=2  
>>> x is y  
False
```

```
>>> s1 = [1, 2, 3, 4]  
>>> s2 = s1  
>>> s2[1] = 17  
>>> s1  
[1, 17, 3, 4]  
>>> s2  
[1, 17, 3, 4]
```

Reference - Example

```
>>> x=1
>>> y=x
>>> x is y
True
>>> y=2
>>> x is y
False
```

```
>>> s1 = [1, 2, 3, 4]
>>> s2 = s1
>>> s2[1] = 17
>>> s1
[1, 17, 3, 4]
>>> s2
[1, 17, 3, 4]
```

Table of Contents

Introduction

Data Types I

Control Statements

Functions

Input/Output

Errors and Exceptions

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

The If Statement

```
if a == 3:  
    print("Aha!")
```

- Blocks are defined by indentation! \Rightarrow *Style Guide for Python*
- Standard: Indentation with four spaces

```
if a == 3:  
    print("spam")  
elif a == 10:  
    print("eggs")  
elif a == -3:  
    print("bacon")  
else:  
    print("something else")
```

Relational Operators

- Comparison of content: `==`, `<`, `>`, `<=`, `>=`, `!=`
- Comparison of object identity: `a is b`, `a is not b`
- And/or operator: `a and b`, `a or b`
- Chained comparison: `a <= x < b`, `a == b == c`, ...
- Negation: `not a`

```
if not (a==b) and (c<3):  
    pass
```

Hint: `pass` is a No Operation (NOOP) function

For Loops

```
for i in range(10):  
    print(i)      # 0, 1, 2, 3, ..., 9  
  
for i in range(3, 10):  
    print(i)      # 3, 4, 5, ..., 9  
  
for i in range(0, 10, 2):  
    print(i)      # 0, 2, 4, 6, 8  
else:  
    print("Loop completed.")
```

- End loop prematurely: `break`
- Next iteration: `continue`
- `else` is executed when loop didn't end prematurely

For Loops (continued)

Iterating directly over sequences (without using an index):

```
for item in ["spam", "eggs", "bacon"]:  
    print(item)
```

The `range` function can be used to create a list:

```
>>> list(range(0, 10, 2))  
[0, 2, 4, 6, 8]
```

If indexes are necessary:

```
for (i, char) in enumerate("hello world"):  
    print(i, char)
```

While Loops

```
i = 0
while i < 10:
    i += 1
```

`break` and `continue` work for while loops, too.

Substitute for do-while loop:

```
while True:
    # important code
    if condition:
        break
```

Table of Contents

Introduction

Data Types I

Control Statements

Functions

Input/Output

Errors and Exceptions

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

Functions

```
def add(a, b):  
    """Returns the sum of a and b."""  
  
    mysum = a + b  
    return mysum
```

```
>>> result = add(3, 5)  
>>> print(result)  
8  
>>> help(add)  
Help on function add in module __main__:  
  
add(a, b)  
    Returns the sum of a and b.
```

Return Values and Parameters

- Functions accept arbitrary objects as parameters and return values
- Types of parameters and return values are unspecified
- Functions without explicit return value return `None`

my_program.py

```
def hello_world():  
    print("Hello World!")  
  
a = hello_world()  
print(a)
```

```
$ python3 my_program.py  
Hello World!  
None
```

Multiple Return Values

Multiple return values are realised using tuples or lists:

```
def foo():  
    a = 17  
    b = 42  
    return (a, b)  
  
ret = foo()  
(x, y) = foo()
```

Optional Parameters – Default Values

Parameters can be defined with default values.

Hint: It is not allowed to define non-default parameters after default parameters

plot_lines.py

```
def fline(x, m=1, b=0): #  $f(x) = m*x + b$ 
    return m*x + b

for i in range(5):
    print(fline(i), end=" ")
#force newline
print()
for i in range(5):
    print(fline(i, -1, 1), end=" ")
```

```
$ python3 plot_lines.py
0 1 2 3 4
1 0 -1 -2 -3
```

Hint: `end` in `print` defines the last character, default is linebreak

Positional Parameters

Parameters can be passed to a function in a different order than specified:

displayPerson.py

```
def printContact(name,age,location):  
    print("Person:  ", name)  
    print("Age:      ", age, "years")  
    print("Address: ", location)  
  
printContact(name="Peter Pan", location="Neverland", age=10)
```

```
$ python3 displayPerson.py  
Person:  Peter Pan  
Age:      10 years  
Address: Neverland
```

Functions are Objects

Functions are objects and as such can be assigned and passed on:

```
>>> a = float
>>> a(22)
22.0
```

```
>>> def foo(fkt):
...     print(fkt(33))
...
>>> foo(float)
33.0
>>> foo(str)
33
>>> foo(complex)
(33+0j)
```

Online Help: Docstrings

- Can be used in function, modul, class and method definitions
- Is defined by a **string** as the first statement in the definition
- `help(...)` on python object returns the docstring
- Two types of docstrings: **one-liners** and **multi-liners**

```
def complex(real=0.0, imag=0.0):  
    """Form a complex number.  
  
    Keyword arguments:  
    real -- the real part (default 0.0)  
    imag -- the imaginary part (default 0.0)  
  
    """  
    ...
```

Functions & Modules

- Functions thematically belonging together can be stored in a separate Python file.
(Same for objects and classes)
- This file is called **module** and can be loaded in any Python script.
- Multiple modules available in the [Python Standard Library](#)
(part of the Python installation)
- Command for loading a module: `import <filename>`
(`filename` without ending `.py`)

```
import math  
s = math.sin(math.pi)
```

More information for standard modules and how to create your own module see chapter Modules and Packages on slide 91

Functions

Input/Output

Errors and Exceptions

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

String Formatting

- Format string + class method `x.format()`
- “replacement fields”: curly braces around optional `arg_name` (default: 0,1,2,...)

```
print("The answer is {0:4d}".format(42))  
'The answer is    42'  
s = "{0}: {1:08.3f}".format("spam", 3.14)  
'spam: 0003.140'
```

format	purpose
	default: string
m.nf	floating point: m filed size, n digits after the decimal point (6)
m.ne	floating point (exponential): m filed size, 1 digit before and n digits behind the decimal point (default: 6)
m.n%	percentage: similar to format f , <i>value</i> * 100 with finalizing '%'
md	Integer number: m field size (0m \Rightarrow leading "0") format d can be replaced by b (binary), o (octal) or x (hexadecimal)

Literal String Interpolation (f-strings)

- Provides a way to embed expressions inside string literals, using a minimal syntax
- Is a literal string, prefixed with 'f', which contains expressions inside braces
- Expressions are evaluated at runtime and replaced with their values.

```
>>> name = "Martin"
>>> age = 50
>>> f"My name is {name} and my age next year is {age+1}"
'My name is Martin and my age next year is 51'
>>> value = 12.345
>>> f"value={value:5.2f}"
'value=12.35'
```

Hint: Since Python 3.6!

String Formatting (deprecated, Python 2 only)

String formatting similar to C:

```
print "The answer is %4i." % 42  
s = "%s: %08.3f" % ("spam", 3.14)
```

- **Integer decimal:** d, i
- **Integer octal:** o
- **Integer hexadecimal:** x, X
- **Float:** f, F
- **Float in exponential form:** e, E, g, G
- **Single character:** c
- **String:** s
- Use %% to output a single % character.

Command Line Input

User input in Python 3:

```
user_input = input("Type something: ")
```

User input in Python 2:

```
user_input = raw_input("Type something: ")
```

Hint: In Python 2 is `input("...")` \iff `eval(raw_input("..."))`

Command line parameters:

```
import sys
print(sys.argv)
```

params.py

```
$ python3 params.py spam
['params.py', 'spam']
```

Files

```
file1 = open("spam.txt", "r")  
file2 = open("/tmp/eggs.json", "wb")
```

- Read mode: `r`
- Write mode (new file): `w`
- Write mode, appending to the end: `a`
- Handling binary files: e.g. `rb`
- Read and write (update): `r+`

```
for line in file1:  
    print(line)
```

Operations on Files

- **Read:** `f.read([size])`
- **Read a line:** `f.readline()`
- **Read multiple lines:** `f.readlines([sizehint])`
- **Write:** `f.write(str)`
- **Write multiple lines:** `f.writelines(sequence)`
- **Close file:** `f.close()`

```
file1 = open("test.txt", "w")
lines = ["spam\n", "eggs\n", "ham\n"]
file1.writelines(lines)
file1.close()
```

Python automatically converts `\n` into the correct line ending!

The with statement

File handling (open/close) can be done by the context manager `with`.
(⇒section [Errors and Exceptions](#) on slide 65).

```
with open("test.txt") as f:  
    for line in f:  
        print(line)
```

After finishing the `with` block the file object is closed, even if an exception occurred inside the block.

Summary and Outlook

Syntax Errors, Indentation Errors

Parsing errors: **Program will not be executed.**

- Mismatched or missing parenthesis
- Missing or misplaced semicolons, colons, commas
- Indentation errors

```
print("I'm running...")  
def add(a, b)  
    return a + b
```

add.py

```
$ python3 add.py  
File "add.py", line 2  
    def add(a, b)  
        ^  
SyntaxError: invalid syntax
```

Exceptions

Exceptions occur at **runtime**:

error.py

```
import math
print("I'm running...")
math.foo()
print("I'm still running...")
```

```
$ python3 error.py
I'm running...
Traceback (most recent call last):
  File "error.py", line 3, in <module>
    math.foo()
AttributeError: module 'math' has no attribute 'foo'
```

Handling Exceptions (1)

```
try:
    s = input("Enter a number: ")
    number = float(s)
except ValueError:
    print("That's not a number!")
```

- `except` block is executed when the code in the `try` block throws an according exception
- Afterwards, the program continues normally
- Unhandled exceptions force the program to exit.

Handling different kinds of exceptions:

```
except (ValueError, TypeError, NameError):
```

Built-in exceptions: <http://docs.python.org/library/exceptions.html>

Handling Exceptions (2)

```
try:
    s = input("Enter a number: ")
    number = 1/float(s)
except ValueError:
    print("That's not a number!")
except ZeroDivisionError:
    print("You can't divide by zero!")
except:
    print("Oops, what's happened?")
```

- Several `except` statements for different exceptions
- Last `except` can be used without specifying the kind of exception: Catches all remaining exceptions
 - Careful: Can mask unintended programming errors!

Handling Exceptions (3)

- `else` is executed if no exception occurred
- `finally` is executed **in any** case

```
try:
    f = open("spam")
except IOError:
    print("Cannot open file")
else:
    print(f.read())
    f.close()
finally:
    print("End of try.")
```

Exception Objects

Access to exception objects:

- `EnvironmentError` (`IOError` , `OSError`):
Exception object has 3 attributes (`errno` , `filename` , `strerror`)
- Otherwise: Exception object is a string

spam_open.py

```
try:
    f = open("spam")
except IOError as e:
    print(e.errno, e.filename, e.strerror)
    print(e)
```

```
$ python3 spam_open.py
2 spam No such file or directory
[Errno 2] No such file or directory: 'spam'
```

Exceptions in Function Calls

- Function calls another function.
- That function raises an exception.
- Is exception handled?
- No: Pass exception to calling function.

Raising Exceptions

Passing exceptions on:

```
try:
    f = open("spam")
except IOError:
    print("Problem while opening file!")
    raise
```

Raising exceptions:

```
def gauss_solver(matrix):
    # Important code
    raise ValueError("Singular matrix")
```

Exceptions vs. Checking Values Beforehand

Exceptions are preferable!

```
def square(x):  
    if type(x) == int or type(x) == float:  
        return x ** 2  
    else:  
        return None
```

- What about other numerical data types (complex numbers, own data types)? Better: Try to compute the power and catch possible exceptions! → **Duck-Typing**
- Caller of a function might forget to check return values for validity. Better: Raise an exception!

Exceptions vs. Checking Values Beforehand

Exceptions are preferable!

```
def square(x):  
    if type(x) == int or type(x) == float:  
        return x ** 2  
    else:  
        return None
```

```
def square(x):  
    return x ** 2  
...  
try:  
    result = square(value)  
except TypeError:  
    print("'{}': Invalid type".format(value))
```

The `with` Statement

Some objects offer context management ³, which provides a more convenient way to write `try ... finally` blocks:

```
with open("test.txt") as f:
    for line in f:
        print(line)
```

After the `with` block the file object is guaranteed to be closed properly, no matter what exceptions occurred within the block.

³Class method `__enter__(self)` will be executed at the beginning and class method `__exit__(...)` at the end of the context

Regular Expressions (optional)

Summary and Outlook

Sets

Set: unordered, no duplicated elements

- `s = {"a", "b", "c"}`

alternative `s = set([sequence])` , required for empty sets.

- **Constant set:** `s = frozenset([sequence])`

e.g. empty set: `empty = frozenset()`

- **Subset:** `s.issubset(t)` , `s <= t` , strict subset: `s < t`

- **Superset:** `s.issuperset(t)` , `s >= t` , strict superset: `s > t`

- **Union:** `s.union(t)` , `s | t`

- **Intersection:** `s.intersection(t)` , `s & t`

- **Difference:** `s.difference(t)` , `s - t`

- **Symmetric Difference:** `s.symmetric_difference(t)` , `s ^ t`

- **Copy:** `s.copy()`

As with sequences, the following works:

```
x in s , len(s) , for x in s , s.add(x) , s.remove(x)
```

Dictionaries

- Other names: [Hash](#), [Map](#), [Associative Array](#)
- Mapping of key → value
- Keys are unordered

```
>>> store = { "spam": 1, "eggs": 17}
>>> store["eggs"]
17
>>> store["bacon"] = 42
>>> store
{'eggs': 17, 'bacon': 42, 'spam': 1}
```

- Iterating over dictionaries:

```
for key in store:
    print(key, store[key])
```

- Compare two dictionaries: `store == pool`
Not allowed: `>`, `>=`, `<`, `<=`

Operations on Dictionaries

- Delete an entry: `del(store[key])`
- Delete all entries: `store.clear()`
- Copy: `store.copy()`
- Does it contain a key? `key in store`
- Get an entry: `store.get(key[, default])`
- Remove and return entry: `store.pop(key[, default])`
- Remove and return arbitrary entry: `store.popitem()`

Operations on Dictionaries

- Delete an entry: `del(store[key])`
- Delete all entries: `store.clear()`
- Copy: `store.copy()`
- Does it contain a key? `key in store`
- Get an entry: `store.get(key[, default])`
- Remove and return entry: `store.pop(key[, default])`
- Remove and return arbitrary entry: `store.popitem()`

Views on Dictionaries

- Create a view: `items()`, `keys()` and `values()`
 - List of all (key, value) tuples: `store.items()`
 - List of all keys: `store.keys()`
 - List all values: `store.values()`
- **Caution:** Dynamical since Python 3

Views Behavior: Python 2.X versus Python 3.X

Python 2 (static)

```
>>> mdict={"a":2, "d":5}
>>> mdict
{'a': 2, 'd': 5}
>>> s=mdict.items()
>>> for i in s:
>>>     print(i)
('a', 2)
('d', 5)
>>> mdict['a']=-1
>>> mdict
{'a': -1, 'd': 5}
>>> for i in s:
>>>     print(i)
('a', 2)
('d', 5)
```

Python 3 (dynamic)

```
>>> mdict={"a":2, "d":5}
>>> mdict
{'a': 2, 'd': 5}
>>> s=mdict.items()
>>> for i in s:
>>>     print(i)
('a', 2)
('d', 5)
>>> mdict['a']=-1
>>> mdict
{'a': -1, 'd': 5}
>>> for i in s:
>>>     print(i)
('a', -1)
('d', 5)
```

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

Object Oriented Programming (OOP)

- So far: **procedural programming**
 - Data (values, variables, parameters, . . .)
 - Functions taking data as parameters and returning results
- Alternative: Group data and functions belonging together to form **custom data types**
- → Extensions of structures in C/Fortran

Using Simple Classes as Structs

my_point.py

```
class Point:
    pass

p = Point()
p.x = 2.0
p.y = 3.3
```

- **Class:** Custom data type (here: `Point`)
- **Object:** Instance of a class (here: `p`)
- Attributes (here `x`, `y`) can be added dynamically

Hint: `pass` is a No Operation (NOOP) function

Classes - Constructor

my_point.py

```
class Point:
    def __init__(self, x, y):
        self.x = x
        self.y = y
```

```
p = Point(2.0, 3.0)
print(p.x, p.y)
p.x = 2.5
p.z = 42
```

- `__init__`: Is called automatically after creating an object

Methods on Objects

my_point.py

```
import math

class Point:
    def __init__(self, x, y):
        self.x = x
        self.y = y

    def norm(self):
        n = math.sqrt(self.x**2 + self.y**2)
        return n

p = Point(2.0, 3.0)
print(p.x, p.y, p.norm())
```

- Method call: automatically sets the object as first parameter
- → traditionally called `self`
- **Careful**: Overloading of methods not possible!

Converting Objects to Strings

Default return value of `str(...)` for objects of custom classes:

```
>>> p = Point(2.0, 3.0)
>>> print(p)    # --> print(str(p))
<__main__.Point instance at 0x402d7a8c>
```

Converting Objects to Strings

Default return value of `str(...)` for objects of custom classes:

```
>>> p = Point(2.0, 3.0)
>>> print(p)    # --> print(str(p))
<__main__.Point instance at 0x402d7a8c>
```

This behaviour can be overwritten:

my_point.py

```
class Point:
    [...]
    def __str__(self):
        return "({0}, {1})".format(self.x, self.y)
```

```
>>> print(p)
(2.0, 3.0)
```

Comparing Objects

Default: `==` checks for object identity of custom objects.

```
>>> p1 = Point(2.0, 3.0)
>>> p2 = Point(2.0, 3.0)
>>> p1 == p2
False
```

Comparing Objects

Default: `==` checks for object identity of custom objects.

```
>>> p1 = Point(2.0, 3.0)
>>> p2 = Point(2.0, 3.0)
>>> p1 == p2
False
```

This behaviour can be overwritten:

my_point.py

```
class Point:
    [...]
    def __eq__(self, other):
        return (self.x == other.x) and (self.y == other.y)
```

```
>>> p1 == p2 # Check for equal values
True
>>> p1 is p2 # Check for identity
False
```

Operator overloading

More relational operators:

- `<` : `__lt__(self, other)`
- `<=` : `__le__(self, other)`
- `!=` : `__ne__(self, other)`
- `>` : `__gt__(self, other)`
- `>=` : `__ge__(self, other)`

Numeric operators:

- `+` : `__add__(self, other)`
- `-` : `__sub__(self, other)`
- `*` : `__mul__(self, other)`
- ...

Emulating Existing Data Types

Classes can emulate built-in data types:

- Numbers: arithmetics, `int(myobj)`, `float(myobj)`, ...
- Functions: `myobj(...)`
- Sequences: `len(myobj)`, `myobj[...]`, `x in myobj`, ...
- Iteratores: `for i in myobj`

See documentation: <http://docs.python.org/3/reference/datamodel.html>

Class Variables

Have the same value for all instances of a class:

my_point.py

```
class Point:
    count = 0 # Count all point objects
    def __init__(self, x, y):
        Point.count += 1 #self.__class__.count += 1
        [...]
```

```
>>> p1 = Point(2, 3); p2 = Point(3, 4)
>>> p1.count
2
>>> p2.count
2
>>> Point.count
2
```

Class Methods and Static Methods

spam.py

```
class Spam:
    spam = "I don't like spam."

    @classmethod
    def cmethod(cls):
        print(cls.spam)

    @staticmethod
    def smethod():
        print("Blah blah.")
```

```
Spam.cmethod()
Spam.smethod()
s = Spam()
s.cmethod()
s.smethod()
```

Inheritance (1)

There are often classes that are very similar to each other.

Inheritance allows for:

- Hierarchical class structure (is-a-relationship)
- Reusing of similar code

Example: Different types of phones

- Phone
- Mobile phone (is a phone with additional functionality)
- Smart phone (is a mobile phone with additional functionality)

Inheritance (2)

```
class Phone:
    def call(self):
        pass

class MobilePhone(Phone):
    def send_text(self):
        pass
```

MobilePhone now inherits methods and attributes from Phone.

```
h = MobilePhone()
h.call() # inherited from Phone
h.send_text() # own method
```

Overwriting Methods

Methods of the parent class can be overwritten in the child class:

```
class MobilePhone(Phone):  
    def call(self):  
        self.find_signal()  
        Phone.call(self)
```

Multiple Inheritance

Classes can inherit from multiple parent classes. Example:

- SmartPhone is a mobile phone
- SmartPhone is a camera

```
class SmartPhone(MobilePhone, Camera):  
    pass  
  
h = SmartPhone()  
h.call() # inherited from MobilePhone  
h.take_photo() # inherited from Camera
```

Attributes are searched for in the following order:

`SmartPhone`, `MobilePhone`, parent class of `MobilePhone` (recursively), `Camera`,
parent class of `Camera` (recursively).

Private Attributes / Private Class Variables

- There are no private variables or private methods in Python.
- **Convention:** Mark attributes that shouldn't be accessed from outside with an underscore: `_foo`.
- To avoid name conflicts during inheritance: Names of the form `__foo` are replaced with `_classname__foo`:

```
class Spam:  
    __eggs = 3  
    _bacon = 1  
    beans = 5
```

```
>>> dir(Spam)  
>>> ['_Spam__eggs', '__doc__', '__module__', '_bacon', 'beans']
```

Classic (old Style) Classes

- The only class type until Python 2.1
- In Python 2 default class

New Style Classes

- Unified class model (user-defined and build-in)
- Descriptors (getter, setter)
- The only class type in Python 3
- Available as basic class in Python 2: **object**

Properties (1)

If certain actions (checks, conversions) are to be executed while accessing attributes, use **getter** and **setter**:

```
class Spam:
    def __init__(self):
        self._value = 0

    def get_value(self):
        return self._value

    def set_value(self, value):
        if value <= 0:
            self._value = 0
        else:
            self._value = value

    value = property(get_value, set_value)
```

Properties (2)

Properties can be accessed like any other attributes:

```
>>> s = Spam()
>>> s.value = 6      # set_value(6)
>>> s.value          # get_value()
6
>>> s.value = -6     # set_value(-6)
>>> s.value          # get_value()
0
```

- Getter and setter can be added later without changing the API
- Access to `_value` still possible

Errors and Exceptions

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

Importing Modules

Reminder: Functions, classes and object thematically belonging together are grouped in modules.

```
import math  
s = math.sin(math.pi)
```

```
import math as m  
s = m.sin(m.pi)
```

```
from math import pi as PI, sin  
s = sin(PI)
```

```
from math import *  
s = sin(pi)
```

Online help: `dir(math)` , `help(math)`

Creating a Module (1)

Every Python script can be imported as a module.

my_module.py

```
"""My first module: my_module.py"""

def add(a, b):
    """Add a and b."""
    return a + b

print(add(2, 3))
```

```
>>> import my_module
5
>>> my_module.add(17, 42)
59
```

Top level instructions are executed during import!

Creating a Module (2)

If instructions should only be executed when running as a script, not importing it:

my_module.py

```
def add(a, b):  
    return a + b  
  
def main():  
    print(add(2, 3))  
  
if __name__ == "__main__":  
    main()
```

Useful e.g. for testing parts of the module.

Creating a Package

Modules can be grouped into hierarchically structured packages.

```
– numeric
  |
  |__init__.py
  |
  | linalg
  |   |
  |   |__init__.py
  |   | decomp.py
  |   | eig.py
  |   | solve.py
  |   |
  |   | fft
  |   |   |
  |   |   |__init__.py
  |   |   | ...
```

- Packages are subdirectories
- In each package directory:
`__init__.py` (may be empty)

```
import numeric
numeric.foo() # from __init__.py
numeric.linalg.eig.foo()
```

```
from numeric.linalg import eig
eig.foo()
```

Modules Search Path

Modules are searched for in (see `sys.path`):

- The directory of the running script
- Directories in the environment variable PYTHONPATH
- Installation-dependent directories

```
>>> import sys
>>> sys.path
['', '/usr/lib/python37.zip',
'/usr/lib64/python3.7',
'/usr/lib64/python3.7/plat-linux', ...]
```

Python's Standard Library

„**Batteries included**“: comprehensive standard library for various tasks

Mathematics: `math`

- Constants: `e`, `pi`
- Round up/down: `floor(x)`, `ceil(x)`
- Exponential function: `exp(x)`
- Logarithm: `log(x[, base])`, `log10(x)`
- Power and square root: `pow(x, y)`, `sqrt(x)`
- Trigonometric functions: `sin(x)`, `cos(x)`, `tan(x)`
- Conversion degree \leftrightarrow radian: `degrees(x)`, `radians(x)`

```
>>> import math
>>> math.sin(math.pi)
1.2246063538223773e-16
>>> math.cos(math.radians(30))
0.86602540378443871
```

Random Numbers: random

- Random integers:

`randint(a, b)`, `randrange([start,] stop[, step])`

- Random floats (uniform distr.): `random()`, `uniform(a, b)`

- Other distributions: `expovariate(lambd)`, `gammavariate(alpha, beta)`, `gauss(mu, sigma)`, ...

- Random element of a sequence: `choice(seq)`

- Several unique, random elements of a sequence: `sample(population, k)`

- Shuffled sequence: `shuffle(seq[, random])`

```
>>> import random
>>> s = [1, 2, 3, 4, 5]
>>> random.shuffle(s)
>>> s
[2, 5, 4, 3, 1]
>>> random.choice("Hello world!")
'e'
```

Time Access and Conversion: `time`

- Classical `time()` functionality
- Time class type is a 9-tuple of `int` values (`struct_time`)
- Time starts at `epoch` (for UNIX: 1.1.1970, 00:00:00)
- Popular functions:
 - Seconds since `epoch` (as a float): `time.time()`
 - Convert time in seconds (float) to `struct_time` : `time.localtime([seconds])`
If seconds is `None` the actual time is returned.
 - Convert `struct_time` in seconds (float): `time.mktime(t)`
 - Convert `struct_time` in formatted string: `time.strftime(format[, t])`
 - Suspend execution of current thread for `secs` seconds: `time.sleep(secs)`

Date and Time: `datetime`

Date and time objects:

```
d1 = datetime.date(2008, 3, 21)
d2 = datetime.date(2008, 6, 22)
dt = datetime.datetime(2011, 8, 26, 12, 30)
t = datetime.time(12, 30)
```

Calculating with date and time:

```
print(d1 < d2)
delta = d2 - d1
print(delta.days)
print(d2 + datetime.timedelta(days=44))
```

Operations on Path Names: `os.path`

- Paths: `abspath(path)`, `basename(path)`, `normpath(path)`, `realpath(path)`
- Construct paths: `join(path1[, path2[, ...]])`
- Split paths: `split(path)`, `splittext(path)`
- File information: `isfile(path)`, `isdir(path)`, `islink(path)`, `getsize(path)`,
...
- Expand home directory: `expanduser(path)`
- Expand environment variables: `expandvars(path)`

```
>>> os.path.join("spam", "eggs", "ham.txt")
'spam/eggs/ham.txt'
>>> os.path.splittext("spam/eggs.py")
('spam/eggs', '.py')
>>> os.path.expanduser("~/spam")
'/home/rbreu/spam'
>>> os.path.expandvars("/mydir/$TEST")
'/mydir/test.py'
```

Files and Directories: `os`

- Working directory: `getcwd()`, `chdir(path)`
- Changing file permissions: `chmod(path, mode)`
- Changing owner: `chown(path, uid, gid)`
- Creating directories: `makedirs(path[, mode])`, `makedirs(path[, mode])`
- Removing files: `remove(path)`, `removedirs(path)`
- Renaming files: `rename(src, dst)`, `renames(old, new)`
- List of files in a directory: `listdir(path)`

```
for myfile in os.listdir("mydir"):  
    os.chmod(os.path.join("mydir", myfile),  
             os.path.stat.S_IRGRP)
```

Files and Directories: `shutil`

Higher level operations on files and directories. Mighty wrapper functions for `os` module.

- Copying files: `copyfile(src, dst)`, `copy(src, dst)`
- Recursive copy: `copytree(src, dst[, symlinks])`
- Recursive removal:
`rmtree(path[, ignore_errors[, onerror]])`
- Recursive move: `move(src, dst)`

```
shutil.copytree("spam/eggs", "../beans",  
                symlinks=True)
```

Directory Listing: glob

List of files in a directory with Unix-like extension of wildcards: `glob(path)`

```
>>> glob.glob("python/[a-c]*.py")
['python/confitest.py',
 'python/basics.py',
 'python/curses_test2.py',
 'python/curses_keys.py',
 'python/cmp.py',
 'python/button_test.py',
 'python/argument.py',
 'python/curses_test.py']
```

Run Processes: subprocess

Simple execution of a program:

```
p = subprocess.Popen(["ls", "-l", "mydir"])  
returncode = p.wait() # wait for p to end
```

Access to the program's output:

```
p = Popen(["ls"], stdout=PIPE, stderr=STDOUT)  
p.wait()  
output = p.stdout.read()
```

Pipes between processes (`ls -l | grep txt`)

```
p1 = Popen(["ls", "-l"], stdout=PIPE)  
p2 = Popen(["grep", "txt"], stdin=p1.stdout)
```

Access to Command Line Parameters: `argparse` (1)

Python program with standard command line option handling:

```
$ ./argumentParser.py -h
usage: argumentParse.py [-h] -f FILENAME [-v]
```

Example how to use argparse

optional arguments:

-h, --help	show this help message and exit
-f FILENAME, --file FILENAME	output file
-v, --verbosity	increase output verbosity

```
$ python3 argumentParse.py -f newfile.txt -v
newfile.txt
True
```

Access to Command Line Parameters: `argparse` (2)

- Simple list of parameters: → `sys.argv`
- More convenient for handling several options: `argparse`
- Deprecated module `optparse` (since Python 2.7/3.2)

`argumentParse.py`

```
parser = argparse.ArgumentParser(  
    description='Example how to use argparse')  
parser.add_argument("-f", "--file",  
                    dest="filename",  
                    default="out.txt",  
                    help="output file")  
parser.add_argument("-v", "--verbosity",  
                    action="store_true",  
                    help="increase output verbosity")  
  
args = parser.parse_args()  
print(args.filename)  
print(args.verbosity)
```

CSV Files: CSV (1)

CSV: Comma Separated Values

- Data tables in ASCII format
- Import/Export by [MS Excel](#) ®
- Columns are delimited by a predefined character (most often comma)

```
f = open("test.csv", "r")
reader = csv.reader(f)
for row in reader:
    for item in row:
        print(item)
f.close()
```

```
f = open(outfile, "w")
writer = csv.writer(f)
writer.writerow([1, 2, 3, 4])
```

CSV Files: CSV (2)

Handling different kinds of formats (dialects):

```
csv.reader(csvfile, dialect='excel') # Default  
csv.writer(csvfile, dialect='excel_tab')
```

Specifying individual format parameters:

```
csv.reader(csvfile, delimiter=";")
```

Further format parameters: `lineterminator`, `quotechar`, `skipinitialspace`, ...

Lightweight Database: `sqlite3` (1)

Database in a file or in memory; in Python's stdlib since 2.5.

```
conn = sqlite3.connect("bla.db")
c = conn.cursor()

c.execute("""CREATE TABLE Friends
            (firstname TEXT, lastname TEXT)""")
c.execute("""INSERT INTO Friends
            VALUES("Jane", "Doe")""")
conn.commit()
```

```
c.execute("""SELECT * FROM Friends""")
for row in c:
    print(row)

c.close();
conn.close()
```

Lightweight Database: `sqlite3` (2)

String formatting is insecure since it allows injection of arbitrary SQL code!

```
# Never do this!  
symbol = "Jane"  
c.execute("... WHERE firstname='{0}'".format(symbol))
```

Lightweight Database: `sqlite3` (3)

Instead: Use the placeholder the database API provides:

```
c.execute("... WHERE name = ?", symbol)
```

```
friends = (("Janis", "Joplin"), ("Bob", "Dylan"))
for item in friends:
    c.execute("""INSERT INTO Friends
                VALUES (?,?)""", item)
```

⇒ Python module `cx_Oracle` to access Oracle database

Web page: <http://cx-oracle.sourceforge.net/>

XML based Client-Server Communication: `xmlrpc` (1)

- XML-RPC: **Remote Procedure Call** uses XML via HTTP
- Independent of platform and programming language
- For the client use `xmlrpc.client`

```
import xmlrpc.client

s = xmlrpc.client.Server("http://localhost:8000")
# print list of available methods
print(s.system.listMethods())
# use methods
print(s.add(2,3))
print(s.sub(5,2))
```

Automatic type conversion for the standard data types: boolean, integer, floats, strings, tuple, list, dictionaries (strings as keys), ...

XML based Client-Server Communication: xmlrpc (2)

- For the server use `xmlrpc.server`

```
from xmlrpc.server import SimpleXMLRPCServer

# methods which are to be offered by the server:
class MyFuncs:
    def add(self, x, y):
        return x + y
    def sub(self, x, y):
        return x - y

# create and start the server:
server = SimpleXMLRPCServer(("localhost", 8000))
server.register_instance(MyFuncs())
server.serve_forever()
```

More Modules

- `readline` : Functionality for command line history and auto-completion
- `tempfile` : Generate temporary files and directories
- `numpy` : **N**umeric **P**ython package
 - N-dimensional arrays
 - Supports linear algebra, Fourier transform and random number capabilities
 - Part of the `SciPy` stack
- `matplotlib` : 2D plotting library, part of the `SciPy` stack
- ...

Introduction

Data Types I

Control Statements

Functions

Input/Output

Errors and Exceptions

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

Conditional Expressions

A conditional assignment as

```
if value < 0:  
    s = "negative"  
else:  
    s = "positive"
```

can be realized in abbreviated form

```
s = "negative" if value < 0 else "positive"
```

List Comprehension

Allows sequences to be build by sequences. Instead of using `for`:

```
a = []  
for i in range(10):  
    a.append(i**2)
```

List comprehension can be used:

```
a = [i**2 for i in range(10)]
```

Conditional values in list comprehension:

```
a = [i**2 for i in range(10) if i != 4]
```

Since [Python 2.7](#): set and dictionary comprehension

```
s = {i*2 for i in range(3)}  
d = {i: i*2 for i in range(3)}
```

Dynamic Attributes

Remember: Attributes can be added to python objects at runtime:

```
class Empty:
    pass

a = Empty()
a.spam = 42
a.eggs = 17
```

Also the attributes can be deleted at runtime:

```
del(a.spam)
```

getattr, setattr, hasattr

Attributes of an object can be accessed by name (string):

```
import math
f = getattr(math, "sin")
print(f(x)) # sin(x)
```

```
a = Empty()
setattr(a, "spam", 42)
print(a.spam)
```

Useful if depending on user or data input.

Check if attribute is defined:

```
if not hasattr(a, "spam"):
    setattr(a, "spam", 42)
print(a.spam)
```

Anonymous Function Lambda

Also known as `lambda expression` and `lambda form`

```
>>> f = lambda x, y: x + y
>>> f(2, 3)
5
>>> (lambda x: x**2)(3)
9
```

Useful if only a simple function is required as an parameter in a function call:

```
>>> friends = ["alice", "Bob"]
>>> friends.sort()
>>> friends
['Bob', 'alice']
>>> friends.sort(key = lambda a: a.upper())
>>> friends
['alice', 'Bob']
```

Functions Parameters from Lists and Dictionaries

```
def spam(a, b, c, d):  
    print(a, b, c, d)
```

Positional parameters can be created by lists:

```
>>> args = [3, 6, 2, 3]  
>>> spam(*args)  
3 6 2 3
```

Keyword parameters can be created by dictionaries:

```
>>> kwargs = {"c": 5, "a": 2, "b": 4, "d": 1}  
>>> spam(**kwargs)  
2 4 5 1
```

Variable Number of Parameters in Functions

```
def spam(*args, **kwargs):  
    for i in args:  
        print(i)  
    for i in kwargs:  
        print(i, kwargs[i])
```

```
>>> spam(1, 2, c=3, d=4)  
1  
2  
c 3  
d 4
```

Global and Static Variables in Functions

- `global` links the given name to a global variable
- Static variable can be defined as an attribute of the function

```
def myfunc():  
    global max_size  
    if not hasattr(myfunc, "_counter"):  
        myfunc._counter = 0    # it doesn't exist yet,  
                               # so initialize it  
  
    myfunc._counter += 1  
    print("{0:d}. call".format(myfunc._counter))  
    print("max size is {0:d}".format(max_size))  
    ...
```

```
>>> max_size = 222  
>>> myfunc()  
1. call  
max size is 222
```

Map

Apply specific function on each list element:

```
>>> li = [1, 4, 81, 9]
>>> mapli = map(math.sqrt, li)
>>> mapli
<map object at 0x7f5748240b90>
>>> list(mapli)
[1.0, 2.0, 9.0, 3.0]
>>> list(map(lambda x: x * 2, li))
[2, 8, 162, 18]
```

Functions with more than one parameter requires an additional list per parameter:

```
>>> list(map(math.pow, li, [1, 2, 3, 4]))
[1.0, 16.0, 531441.0, 6561.0]
```

Filter

Similar to `map`, but the result is a `filter` object, which contains only list elements, where the function returns `True`.

filter_example.py

```
li = [1, 2, 3, 4, 5, 6, 7, 8, 9]
liOdd = filter(lambda x: x % 2, li)
print("li =", li)
print("liOdd =", liOdd)
print("list(liOdd) =", list(liOdd))
```

```
$ python3 filter_example.py
li = [1, 2, 3, 4, 5, 6, 7, 8, 9]
liOdd = <filter object at 0x7fe4ccdc7c0>
list(liOdd) = [1, 3, 5, 7, 9]
$
```

Zip

- Join multiple sequences to one list of tuples:
Useful when iterating on multiple sequences in parallel

```
>>> list(zip("ABC", "123"))  
[('A', '1'), ('B', '2'), ('C', '3')]  
>>> list(zip([1, 2, 3], "ABC", "XYZ"))  
[(1, 'A', 'X'), (2, 'B', 'Y'), (3, 'C', 'Z')]
```

- Example: How to create a dictionary by two sequences

```
>>> dict(zip(("apple", "peach"), (2,0)))  
{ 'apple': 2, 'peach': 0 }
```

Iterators (1)

What happens, if `for` is applied on an object?

```
for i in obj:  
    pass
```

- The `__iter__` method for `obj` is called, return an **iterator**.
- On each loop cycle the `iterator.__next__()` method will be called.
- The exception `StopIteration` is raised when there are no more elements.
- Advantage: Memory efficient (access time)

Iterators (2)

```
class Reverse:
    def __init__(self, data):
        self.data = data
        self.index = len(data)
    def __iter__(self):
        return self
    def __next__(self):
        if self.index == 0:
            self.index = len(self.data)
            raise StopIteration
        self.index = self.index - 1
        return self.data[self.index]
```

```
>>> for char in Reverse("spam"):
...     print(char, end=" ")
...
m a p s
```

Generators

Simple way to create iterators:

- Methods uses the `yield` statement
⇒ breaks at this point, returns element and continues there on the next `iterator.__next__()` call.

```
def reverse(data):  
    for element in data[::-1]:  
        yield element
```

```
>>> for char in reverse("spam"):  
...     print(char, end=" ")  
...  
m a p s
```

Generator Expressions

Similar to the [list comprehension](#) an [iterator](#) can be created using a [generator expression](#):

```
>>> data = "spam"
>>> for c in (elem for elem in data[::-1]):
...     print(c, end=" ")
...
m a p s
```

Data Types I

Control Statements

Functions

Input/Output

Errors and Exceptions

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

IPython (I)

- Enhanced interactive Python shell
- Numbered input/output prompts
- Object introspection

```
In [1]: len?  
Type:      builtin_function_or_method  
String Form: <built-in function len>  
Namespace: Python builtin  
Docstring:  
len(object)  
  
Return the number of items of a sequence or collection.
```

- System shell access

```
In [1]: a = !ls  
  
In [2]: print(a)  
['example01.py', 'example02.py', 'example03.py']
```

IPython (II)

- Tab-completion
- Command history retrieval across session
- User-extensible 'magic' commands
 - `%timeit` ⇒ Time execution of a Python statement or expression using the timeit module
 - `%cd` ⇒ Change the current working directory
 - `%edit` ⇒ Bring up an editor and execute the resulting code
 - `%run` ⇒ Run the named file inside IPython as a program
 - ⇒ *more 'magic' commands*
- ⇒ *IPython documentation*

PIP Installs Python/Packages (I)

- Command `pip`
- A tool for installing Python packages
- Python 2.7.9 and later (on the python2 series), and Python 3.4 and later include `pip` by default
- Installing Packages

```
$ pip3 install SomePackage
$ pip3 install --user SomePackage      #user install
```

- Uninstall Packages

```
$ pip3 uninstall SomePackage
```

PIP Installs Python/Packages (II)

■ Listing Packages

```
$ pip3 list
docutils (0.9.1)
Jinja2 (2.10)
Pygments (2.3.1)
Sphinx (1.1.2)
$ pip3 list --outdated
docutils (Current: 0.9.1 Latest: 0.14)
Sphinx (Current: 1.1.2 Latest: 2.10)
```

■ Searching for Packages

```
$ pip3 search "query"
```

■ \Rightarrow *pip documentation*

pyenv - Simple Python Version Management (I)

- Easily switch between multiple versions of Python
- Doesn't depend on Python itself
- Inserts directory of *shims*⁴ at the front of your `PATH`
- Easy Installation:

```
$ git clone https://github.com/yyuu/pyenv.git ~/.pyenv
$ echo 'export PYENV_ROOT="$ HOME/.pyenv"' >> ~/.bashrc
$ echo 'export PATH="$ PYENV_ROOT/bin: $ PATH"' >> ~/.bashrc
$ echo 'eval " $ (pyenv init -)"' >> ~/.bashrc
```

- ⇒ *pyenv repository*

⁴kind of infrastructure to redirect system/function calls
metaphor: A *shim* is a piece of wood or metal to make two things fit together

pyenv - Simple Python Version Management (II)

- Install Python versions into `$PYENV_ROOT/versions`

```
$ pyenv install --list      # available Python versions
$ pyenv install 3.7.4      # install Python 3.7.4
```

- Change the Python version

```
$ pyenv global 3.7.4      # global Python
$ pyenv local 3.7.4       # per-project Python
$ pyenv shell 3.7.4       # shell-specific Python
```

- List all installed Python versions (asterisk shows the active)

```
$ pyenv versions
system
2.7.16
* 3.7.4 (set by PYENV_VERSION environment variable)
```

Virtual Environments

- Allow Python packages to be installed in an isolated location
- Use cases
 - Two applications need different versions of a library
 - Install an application and leave it be
 - Can't install packages into the global site-packages directory
- Virtual environments have their own installation directories
- Virtual environments don't share libraries with other virtual environments
- Available implementations:
 - `virtualenv` (Python 2 and Python 3)
 - `venv` (Python 3.3 and later)

venv

- Create virtual environment

```
$ python3 -m venv /path/to/env
```

- Activate

```
$ source /path/to/env/bin/activate
```

- Deactivate

```
$ deactivate
```

- \Rightarrow *venv documentation*

Pylint (I)

- `pylint` is the `lint` implementation for python code
- Checks for errors in Python code
- Tries to enforce a coding standard
- Looks for bad code smells
- Displays classified messages under various categories such as errors and warnings
- Displays statistics about the number of warnings and errors found in different files

Pylint (II)

- The code is given an overall mark

```
$ python3 -m pylint example.py

...

Global evaluation
-----
Your code has been rated at 10.00/10
                        (previous run: 9.47/10, +0.53)
```

- \Rightarrow *Pylint documentation*

Software testing

- Part of quality management
- Point out the defects and errors that were made during the development phases
- It always ensures the users or customers satisfaction and reliability of the application
- The cost of fixing the bug is larger if testing is not done \Rightarrow testing saves time
- Python testing tools
 - pytest
 - unittest
 - ...

pytest

- Easy to get started
- `test_` prefixed test functions or methods are test items
- Asserting with the `assert` statement
- pytest will run all files in the current directory and its subdirectories of the form `test_*.py` or `*_test.py`
- Usage:

```
$ python3 -m pytest
...
$ python3 -m pytest example.py
...
```

- \Rightarrow *pytest documentation*

pytest Example: Check Function Return Value

example1_test.py

```
def incr(x):  
    return x + 11  
  
def test_incr():  
    assert incr(3) == 4
```

```
$ python3 -m pytest -v example1_test.py  
...  
----- test_incr -----  
def test_incr():  
>       assert incr(3) == 4  
E       assert 14 == 4  
E       +   where 14 = incr(3)  
  
example1_test.py:5: AssertionError  
===== 1 failed in 0.00 seconds =====
```

pytest Example: Check for expected Exception

```
import pytest

def f():
    raise SystemExit(1)

def test_error():
    with pytest.raises(SystemExit): #passes
        f()
```

pytest Example: Check for expected Exception

```
import pytest

def f():
    raise SystemExit(1)

def test_error():
    with pytest.raises(SystemExit): #passes
        f()
```

pytest Example: Comparing Two Data Object

```
def test_list_comparison():
    list1 = [1,3,0,8]
    list2 = [1,3,3,8]
    assert list1 == list2 #fails
```

pytest Example: Parameterize Test Function

```
def incr(x):  
    return x + 1  
  
@pytest.mark.parametrize("test_input, expected", [  
    (1, 2),  
    (2, 3),  
    (3, 4),  
)  
def test_incr(test_input, expected):  
    assert incr(test_input) == expected
```

Introduction

Data Types I

Control Statements

Functions

Input/Output

Errors and Exceptions

Data Types II

Object Oriented Programming

Modules and Packages

Advanced Techniques

Tools

Regular Expressions (optional)

Summary and Outlook

Regular Expressions – Introduction

- Regular expression (RegExp):
Formal language for pattern matching in strings
- Motivation: Analyze various text files:
 - Log files
 - Data files (e.g. experimental data, system configuration, ...)
 - Command output
 - ...
- Python module: `import re`

```
>>> re.findall(r"a.c", "abc aac aa abb a c")  
['abc', 'aac', 'a c']
```

Remember:

`r"..."` \Rightarrow raw string (escape sequences are not interpreted)

Regular Expressions – Character Classes

- Class/set of possible characters: `[!?:.,;a-z]`
- `^` at the beginning negates the class.
e.g.: `[^aeiou]` \Rightarrow all characters besides the vocals
- Character class in pattern tests for **one** character
- The `.` represents **any** (one) character
- Predefined character classes:

name	character	Acr.	negated
whitespace	<code>[\t\n\r\f]</code>	<code>\s</code>	<code>\S</code>
word character	<code>[a-zA-Z_0-9]</code>	<code>\w</code>	<code>\W</code>
digit	<code>[0-9]</code>	<code>\d</code>	<code>\D</code>

```
>>> re.findall(r"\s\d\s", "1 22 4 22 1 a b c")
[' 4 ', ' 1 ']
>>> re.findall(r"[^aeiou]", "Python Kurs")
['P', 'y', 't', 'h', 'n', ' ', 'K', 'r', 's']
```

Regular Expressions – Quantifiers

- Quantifier can be defined in ranges (min, max):

`\d{5,7}` matches sequences of 5-7 digits

- Acronym:

		Default
<code>{1}</code>	one-time occurrence	
<code>{0,}</code>	none to multiple occurrences	<code>*</code>
<code>{0,1}</code>	none or one-time occurrence	<code>?</code>
<code>{1,}</code>	at least one-time occurrence	<code>+</code>

```
>>> re.findall(r"[ab]{1,2}", "a aa ab ba bb b")
['a', 'aa', 'ab', 'ba', 'bb', 'b']
>>> re.findall(r"\d+", "1. Python Kurs 2012")
['1', '2012']
```

Regular Expressions – Anchors

- Anchors define special restrictions to the pattern matching:

\b	word boundary, switch between \w and \W
\B	negate \b
^	start of the string
\$	end of the string

```
>>> re.findall(r"^d+", "1. Python Course 2015")  
['1']
```

- Look-around anchors (context):

- Lookahead

ab(?=c) matches "ab" if it's part of "abc"

ab(?!c) matches "ab" if not followed by a "c"

- Lookbehind

(?<=c)ab matches "ab" if it's part of "cab"

(?<!c)ab matches "ab" if not behind a "c"

Regular Expression – Rules for Pattern Matching

- Pattern analysis will start at the beginning of the string.
- If pattern matches, analysis will continue as long as the pattern is still matching (**greedy**).
- Pattern matching behavior can be changed to **non-greedy** by using the "?" behind the quantifier.
⇒ the pattern analysis stops at the first (minimal) matching

```
>>> re.findall(r"Py.*on", "Python ... Python")
['Python ... Python']
>>> re.findall(r"Py.*?on", "Python ... Python")
['Python', 'Python']
```

Regular Expressions – Groups

- `()` brackets in a pattern create a group
- Group name is numbered serially (starting with 1)
- The first 99 groups (`\1` - `\99`) can be referenced in the same pattern
- Patterns can be combined with logical **or** (`|`) inside a group

```
>>> re.findall(r"(\w+) \1", "Py Py abc Test Test")
['Py', 'Test']
>>>
>>> re.findall(r"([A-Za-z]+\d+)", "uid=2765(zdv124)")
['uid', '2765', 'zdv', '124']
>>>
>>> re.findall(r"(\.[*?\\]|<.*?>)", "[hi]s<b>sd<hal>")
['[hi]', '<b>', '<hal>']
```

Regular Expressions – Group Usage

- Some `re.*` methods return a `re.MatchObject`
⇒ contain captured groups

re_groups.py

```
text="adm06:x:706:1000:St.Graf:/home/adm06:/bin/bash"
grp=re.match(
    r"^([a-z0-9]+):x:[0-9]+:[0-9]+:(.+):.+:$",text)
if (grp):
    print("found:", grp.groups())
    print(" user ID=",grp.group(1))
    print(" name=",grp.group(2))
```

```
$ python3 re_groups.py
found: ('adm06', 'St.Graf')
user ID= adm06
name= St.Graf
```

Regular Expressions – Matching Flags

- Special flags can change behavior of the pattern matching
 - `re.I`: Case insensitive pattern matching
 - `re.M`: `^` or `$` will match at beginning/end of each line (not only at the beginning/end of string)
 - `re.S`: `.` also matches newline (`\n`)

```
>>> re.findall("^abc", "Abc\nabc")
[]
>>> re.findall("^abc", "Abc\nabc", re.I)
['Abc']
>>> re.findall("^abc", "Abc\nabc", re.I|re.M)
['Abc', 'abc']
>>> re.findall("^Abc.", "Abc\nabc")
[]
>>> re.findall("^Abc.", "Abc\nabc", re.S)
['Abc\n']
```

Regular Expressions – Methods (I)

findall: Simple pattern matching

⇒ list of strings (hits)

```
>>> re.findall(r"\[.*?\]", "a[bc]g[hal]def")  
['[bc]', '[hal]']
```

sub: Query replace ⇒ new (replaced) string

```
>>> re.sub(r"\[.*?\]", "!", "a[bc]g[hal]def")  
'a!g!def'
```

search: Find first match of the pattern

⇒ returns `re.MatchObject` or `None`

```
if re.search(r"\[.*?\]", "a[bc]g[hal]def"):  
    print("pattern matched!")
```

Regular Expressions – Methods (II)

match: Starts pattern matching at beginning of the string

⇒ returns `re.MatchObject` or `None`

```
text="adm06:x:706:1000:St.Graf:/home/adm06:/bin/bash"  
grp=re.match(  
    "([a-z0-9]+):x:[0-9]+:[0-9]+:(.+):.+:.+$",text)
```

compile: Regular expressions can be pre-compiled

⇒ gain performance on reusing these `RegExp` multiple times
(e.g. in loops)

```
>>> pattern = re.compile(r"\[.*?\]")  
>>> pattern.findall("a[bc]g[hal]def")  
['[bc]', '[hal]']
```

Summary and Outlook

Summary

We have learned:

- Multiple **data types** (e.g. „high level“)
- Common **statements**
- Declaration and usage of **functions**
- **Modules** and packages
- Errors and **Exceptions**, exception handling
- **Object oriented programming**
- Some of the often used standard modules
- Popular tools for Python developers

Not covered yet

- Closures, decorators (function wrappers)
- Meta classes
- More standard modules: mail, WWW, XML, ...
→ <https://docs.python.org/3/library>
- Profiling, debugging, unit-testing
- Extending and embedding: Python & C/C++ → <https://docs.python.org/3/extending>
- Third Party-Modules: Graphic, web programming, data bases,
... → <http://pypi.python.org/pypi>

Web Programming

- CGI scripts: Module `cgi` (standard lib)
- Web frameworks: Django, Flask, Pylons, ...
- Template systems: Cheetah, Genshi, Jinja, ...
- Content Management Systems (CMS): Zope, Plone, Skeletonz, ...
- Wikis: MoinMoin, ...

The MoinMoin Wiki Engine

Overview

[MoinMoin](#) is an advanced, easy to use and extensible [WikiEngine](#) with a large community of users. Said in a few words, it is about collaboration on easily editable web pages. MoinMoin is Free Software licensed under the [GPL](#).

- If you want to learn more about wiki in general, first read about [WikiWikiWeb](#), then about [WhyWikiWorks](#) and the [WikiNature](#).
- If you want to play with it, please use the [WikiSandBox](#).
- [MoinMoinFeatures](#) documents why you really want to use MoinMoin rather than another wiki engine.
- [MoinMoinScreenShots](#) shows how it looks like. You can also browse *this* wiki or visit some other [MoinMoinWikis](#).

NumPy + SciPy + Matplotlib = Pylab

Alternative to MatLab:

Matrix algebra, numeric functions, plotting, ...

And more ...

- **jupyter** Notebook (interactive computational environment)
- Python IDEs
 - PyCharm
 - Eclipse (PyDev)
 - ...
- Python and other languages:
 - Jython: Python code in Java VM
 - Ctypes: Access C-libraries in Python (since 2.5 in standard lib)
 - SWIG: Access C- and C++ -libraries in Python
- **PIL**: [Python Imaging Library](#) for image manipulation
- **SQLAlchemy**: ORM-Framework
 - Abstraction: Object oriented access to database

Interactive High-Performance Computing with Jupyter

PRACE-Trainingskurs, online (20.04,, - 22.04.202)

- Introduction to Jupyter
- Parallel computing using Jupyter
- Coupling and control of simulations
- Interactive and in-situ visualization
- Simulation dashboards
- <https://www.fz-juelich.de/SharedDocs/Termine/IAS/JSC/DE/Kurse/2021/ptc-interactive-hpc-2021.html?nn=717802>

Data Analysis and Plotting in Python with Pandas

Trainingskurs, online (27.05.2021)

- Introduction to Pandas
- Simple examples
- Hands-on exercises
- <https://www.fz-juelich.de/SharedDocs/Termine/IAS/JSC/DE/Kurse/2021/pandas-2021.html?nn=717802>

High-performance computing with Python

PRACE-Trainingskurs, online (07.06. - 11.06.2021)

- Introduces Matlab programmers to the usage of Python

- 1 Interactive parallel programming with IPython
- 2 Profiling and optimization
- 3 High-performance NumPy
- 4 Just-in-time compilation with numba
- 5 Distributed-memory parallel programming with Python and MPI
- 6 Bindings to other programming languages and HPC libraries
- 7 Interfaces to GPUs
- 8 <https://www.fz-juelich.de/SharedDocs/Termine/IAS/JSC/DE/Kurse/2021/ptc-hpc-python-2021.html?nn=717802>
